

Tirai — ideal customer profile & audience

Who trades on a confidential RFQ desk, who pays for it, and who is deliberately not the customer.

HackCanton Season #2 · Financial Applications · solo builder: Pugar Huda Mantoro · repo github.com/PugarHuda/tirai · live desk tirai.vercel.app

THE ONE-LINE ICP

A trading desk that moves single tickets large enough to move the price, in an asset that is already tokenised (or about to be), and that is required to evidence best execution to someone. All three conditions must hold: size creates the leak, tokenisation makes on-ledger settlement possible, and the evidence requirement is why they cannot simply trade in a private chat.

Below roughly \$1m a ticket, information leakage is a rounding error and a public order book is fine — those users are not the customer. Tirai earns its keep exactly where the spread lost to signalling exceeds every other cost of trading.

PRIMARY SEGMENTS

Segment	Who signs	The pain today	Why now
Buy-side fixed income — asset managers, insurers, pension funds trading sovereigns, supranationals and IG credit	Head of trading / COO of the desk; compliance signs off	RFQ to 5 dealers on a phone or a closed terminal; no atomic settlement, T+1/T+2 risk, manual reconciliation, best-execution evidence assembled after the fact	Their bonds are becoming tokenised; they need a venue that does not leak, or they simply will not trade the tokenised line
Sell-side dealer desks — bank rates/credit desks, market makers, ETF and RWA liquidity providers	Desk head; e-trading lead	Quotes visible to rivals get faded and picked off; showing a price on-chain means showing the whole market your axe	They want to quote tokenised inventory without publishing their book — sealed quotes make on-chain market making survivable
Crypto-native institutional desks — funds, treasuries and prop shops trading cETH / CBTC in size	CIO / head of trading (short chain of command — fastest to pilot)	Large on-chain transfers are watched in real time; mempool visibility and wallet surveillance turn a block trade into a public event	cETH and CBTC exist now and settle on Canton; the desk they need to trade them confidentially does not
Venues & hosting apps — Temple, Bron, Console, Canton Loop (channel, not end user)	Product lead / BD	They have distribution and custody but no confidential RFQ primitive to offer their institutional users	Tirai plugs in as an app and shares the per-trade fee — the fastest route to real users

Regulators & compliance (mandatory third party, not a payer)	Head of compliance; supervisory authority	Either total opacity (off-chain voice trading) or total exposure (public chain). Nothing in between	Post-trade-only visibility plus on-demand quote disclosure is exactly the middle they have been asking for
---	--	--	--

FIRMOGRAPHICS OF THE IDEAL FIRST CUSTOMER

- **Ticket size:** \$1m–\$100m notional per trade; anything smaller does not leak enough to care.
- **Asset:** tokenised government or corporate bonds, or cETH / CBTC — an asset with a real registry on Canton, so the cash leg is a CIP-56 asset rather than an IOU.
- **Panel size:** 3–8 dealers. Enough for competitive pricing, small enough that every participant is known and onboarded.
- **Regulatory posture:** subject to best-execution or transaction reporting obligations (MiFID II RTS 27/28-style, or an internal equivalent). This is a feature, not an obstacle: the requirement is what rules out a private chat.
- **Technical posture:** already runs — or is willing to be hosted on — a Canton validator, and holds assets in a wallet that supports the token standard's allocation flow.
- **Geography:** wherever tokenised issuance is already live — EU/UK and Singapore first, then US and Middle East institutional desks.

JOBS TO BE DONE

- "Get me a competitive price on this block *without* telling the market I am a seller."
- "Make sure the asset and the cash move together, so I am not carrying settlement risk against a counterparty I just met."
- "Let me prove to compliance — months later — that I got the best price available, without having published my order."
- (Dealer) "Let me show a real price to one client without showing my axe to my competitors."
- (Regulator) "Give me a complete record of what was executed, without giving me a live feed of everything that was merely contemplated."

WHO IS EXPLICITLY NOT THE AUDIENCE

- **Retail and small-ticket flow.** An AMM or a public order book is cheaper and better for them; sealed quotes solve a problem they do not have.
- **Anonymous / permissionless counterparties.** Tirai's privacy is *selective*, not anonymity: every party is a known, onboarded institution, and the regulator sees every executed trade. Anyone who wants to hide from a supervisor is a bad fit by design.
- **High-frequency and continuous two-sided markets.** RFQ is an episodic, negotiated workflow; microsecond central-limit-order-book trading is a different product.

- **Desks with no tokenised asset.** Without a real registry on the other side, this is a private chat with extra steps.

REACHING THEM

Beachhead: crypto-native institutional desks trading cETH and CBTC. Short decision chains, assets already on Canton, and pain they feel weekly — the fastest path to a live pilot with real volume.

Expansion: from that reference, into tokenised-bond desks at asset managers, arriving through the venue rather than cold: Tirai ships as an app inside a hosting venue (Temple, Bron, Console, Canton Loop) that already holds the client relationship and the custody. The venue takes distribution; Tirai takes the per-trade fee in the settlement asset.

Design-partner profile for the first pilot: one desk that trades a single instrument class in size, a panel of 3–5 dealers it already faces bilaterally, and a compliance function willing to accept an on-ledger post-trade record in place of its current spreadsheet.

Tirai — Indonesian for "curtain". Price discovery happens behind it. You whisper quotes; the market hears nothing.
